# Dictionary Objects

## Outline

---

# Practice Exercises

# Motivation

---

- What if we wanted to store student records and access them by student ID?
  - We could maintain a list, but this will be inefficient
  - Here, we can use dictionaries
- What if we wanted to store the employer name along with the job application due date?
  - Here, we can use dictionaries

# Dictionary

- A dictionary is a collection of key, value pairs. The key is like a name of the element that allows quick access to it.
  - From our motivating example of a student record – the key is a student ID and the entire student data is the value

# Creating a Dictionary

- Again there are various ways to make a dictionary:
  - `d1 = {}` # Create an empty dictionary
  - `d2 = {"john":40, "peter":45}` # Create a dictionary
- When listing the elements, the first literal is a key and the second literal is the value (separated by a :)

# Adding/Modifying Entries

- To add or modify an entry to a dictionary:
  - `dictionary[key] = value`
- For example:
  - `d2["susan"] = 50`

# Deleting Entries

- To delete an entry from a dictionary:
  - `del dictionary[key]`
- For example:
  - `del d2["susan"]`

# Looping over Entries

- A for loop over a dictionary will loop over its keys. As an example:

```
for key in dictionary:  
    print(key + ":" + str(dictionary[key]))
```

# Operations with dictionaries

- Similar operations exist for dictionaries as did other data structures
  - `len(dict)` counts the number of entries into the dictionary
  - `in/not in` tests existence of keys
- Other methods:

dict	
<code>keys(): tuple</code>	Returns a sequence of keys.
<code>values(): tuple</code>	Returns a sequence of values.
<code>items(): tuple</code>	Returns a sequence of tuples (key, value).
<code>clear(): void</code>	Deletes all entries.
<code>get(key): value</code>	Returns the value for the key.
<code>pop(key): value</code>	Removes the entry for the key and returns its value.
<code>popitem(): tuple</code>	Returns a randomly-selected key/value pair as a tuple and removes the selected entry.

# Practice with Dictionary Functions

```
>>> students={}
```

```
>>>students={101:"John",102:"Peter",103:"Mary",104:"Emily"}
```

```
>>> students[101]="John Smith"
```

```
>>> students
```

```
{101: 'John Smith', 102: 'Peter', 103: 'Mary', 104: 'Emily' }
```

```
>>> del students[102]
```

```
>>> students
```

```
{101: 'John Smith', 103: 'Mary', 104: 'Emily' }
```

# Practice with Dictionary Functions

```
>>> for key in students:  
    print(key, students[key])
```

```
101 John Smith
```

```
103 Mary
```

```
104 Emily
```

# Practice with Dictionary Functions

```
>>> students.keys()  
dict_keys([101, 103, 104])
```

```
>>> students.values()  
dict_values(['John Smith', 'Mary', 'Emily'])
```

```
>>> students.items()  
dict_items([(101, 'John Smith'), (103, 'Mary'),  
(104, 'Emily')])
```

# Practice with Dictionary Functions

```
>>> for key,value in students.items():  
    print(key,value)
```

```
101 John Smith
```

```
103 Mary
```

```
104 Emily
```

# Practice with Dictionary Functions

```
>>> len(students)
```

```
3
```

```
>>> 102 in students
```

```
False
```

```
>>> 101 in students
```

```
True
```

```
>>> students.get(103)
```

```
'Mary'
```

# Practice with Dictionary Functions

```
>>> students.update({104: 'Emma'})
```

```
>>> students  
{101: 'John Smith', 103: 'Mary', 104: 'Emma'}
```

```
>>> students.clear()
```

```
>>> students  
{}
```

# Practice Exercise 1

- Given a dictionary (dict1) with key-value pair, write a program that would generate a new dictionary (dict2) with key as value of dict1 and value as value from dict1 multiplied by 5.

Sample run:

Initial dictionary

```
{1: 11, 2: 22, 3: 33, 4: 44, 5: 55}
```

Updated dictionary

```
{11: 55, 22: 110, 33: 165, 44: 220, 55: 275}
```

# Practice Exercise 2

- Write a Python script to concatenate following dictionaries to create a new one.

Example:

```
dict1={1:10, 2:20}
```

```
dict2={3:30, 4:40}
```

```
dict3={5:50, 6:60}
```

```
Expected Result : {1: 10, 2: 20, 3: 30, 4: 40, 5:  
50, 6: 60}
```

# Practice Exercise 3

- Write a Python script to check whether a given key already exists in a dictionary.

Thank you!
